

Android Project Analysis - Death Notices

by Neil Grogan 13204052

Abstract

This report details the creation of a death notices application for older people, on the Android platform. It was done as a proof of concept and to learn about the android platform from a development point of view.

Application Overview

Introduction

I have created an application for death notices. It caters to a market often left out by the digital revolution: older people. It is also a pretty unique application for the Irish market, as I will show.

Design Aims

The main aims of my chosen app design is as follows:

- to be easy to use
- to be clearly laid out and use simple language
- to use big touch areas (for those with dexterity issues)

Although these design aims sound easy, it is actually harder to cut functionality and features as a developer. This is essential however to keep the audience for the application in mind.

Research

Before starting to write the application, I did market research to find similar applications. Surprisingly, there are not many applications in this particular area.

Key information

I also started to critically analyse the existing websites in Ireland for what they did well or what seemed to work. Clear themes soon emerged:

- rip.ie was the most trusted, as it is updated by funeral directors. This means that their data reliability was second-to-none. This came as a surprise due to the other larger players in this market.
- Search seemed to entirely revolve around name or place
- Business models seemed to be:
 - Charge per notice
 - Charge funeral directors a monthly fee
 - Carry advertisements
- Single purpose websites, even when part of a larger business

Selected Similar Applications

I trawled the Google Play Store with keywords similar to those I would use to describe my application. I managed to find the following:

Application Name	Purpose	Of Interest to Design
Old Maid Card Game	A victorian card game for 2–8 players whereby the person who gets a Queen Card is the Old Maid and loses the game	Very Simple to use; Language easy to understand; Everything is Big; Very colourful and simple basic instructions.
Obituary App	American Based - Directly comparative	Picture of the person, Sentence of something important/meaningful they did, Very nicely laid out, Very colourful and also nice and big.
The Funeral App		Ability to chose the city/town/village you live in, notifications of new obituaries added, also very colourful and nicely laid out.
Old Person App		A magnifying glass, flashlight and large-print notebook in one simple app. Very big and colourful, easy to understand, big writing and big buttons.
Heaven Address		You can search for memorials online (most likely taking you to a website outside of app) as-well as viewing upcoming funerals, Ability to view obituaries and funeral notices, Ability to share content with facebook, Photo Albums and a guestbook for people to leave messages on. It looks lovely, very appealing to the eye, easy to navigate. Also very important it is readable so therefore an older person or poorly sighted person can read it with ease.

Creating the Application

Introduction

I started creating the application by deciding on the data. This meant writing a ruby script to parse rip.ie and deciding how to feed this to the application. One of the lightest ways to do this is using JSON, and Android has great inbuilt support for JSON.

Data

Scraping the Data

To scrape the data, I settled on using a scripting language. I decided against using Java, as the script would be entirely separate from the application (and not used for grading). So I settled on either Python (with BeautifulSoup) or Ruby (with Nokogiri). As I haven't done as much coding in Ruby, I decided to make a change and use it to try parse rip.ie.

Data Flow

Data is fed to the app using a JSON (JavaScript Object Notation) file, which has an array of objects, and each of these objects represents a death notice. Here is one such death notice in JSON format:

```
[{"id":250900,
"first_name":"Milo",
"last_name":"Grogan",
"address":"Fiacres Place, Kilkenny",
"lat":"52.8543023",
"lon":"-7.428077500000001",
"text":"Milo Grogan of Kilkenny was a great person",
"date_of_death":"2015-03-12","date_published":"2015-03-13"}]
```

and is converted to a Java Object by Google's GSON Library:

```
public class Notice {

@SerializedName("id")
public int id;
public String first_name;
public String last_name;
public String address;
public String lat;
```

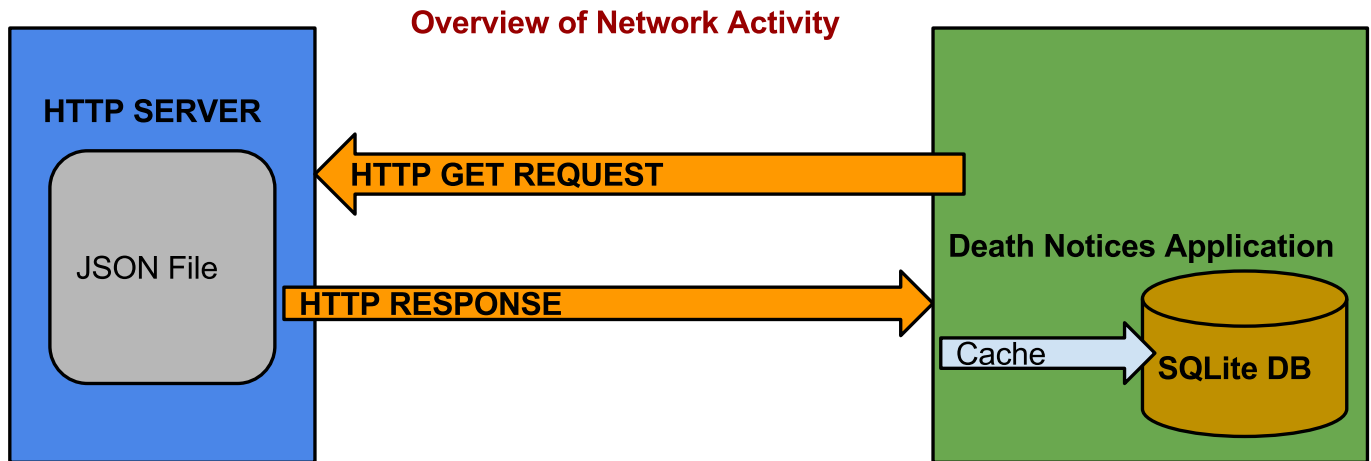

```

public String lon;
public String text;
public Date date_of_death;
public Date date_published;

..getters and setters..
}

```

The java object is then used internally by the application to display data and add to the database:

The JSON file is hosted on a HTTP Server and is generated by scraping a death notices website, rip.ie. The script is written in Ruby Language, as it is easy to do quick tasks with. To access the JSON file, the application requires the internet permission from the Android OS, and this is specified in the manifest.

Data Storage

Data is cached locally in an SQLite database. The reason for this is fourfold:

- to lessen memory (RAM) usage
- to lessen network usage
- to use less code (SQLite is inbuilt to Android)
- to enable native queries

Network and Memory are expensive on personal devices such as phones. To keep the app simple, I opted to choose lightweight data (JSON) in to a lightweight database (SQLite), both extensively supported on the Android platform.

Data Queries

As a user, the queries I want to do with the app are very “structured” (and simple). The most common way of searching death notices is either by name (if you already know someone whom is deceased) or by area (if your browsing). This

made SQLite a great choice, as any SQL-based database would be. This is opposed to other apps where full-text search might be easier with NOSQL options.

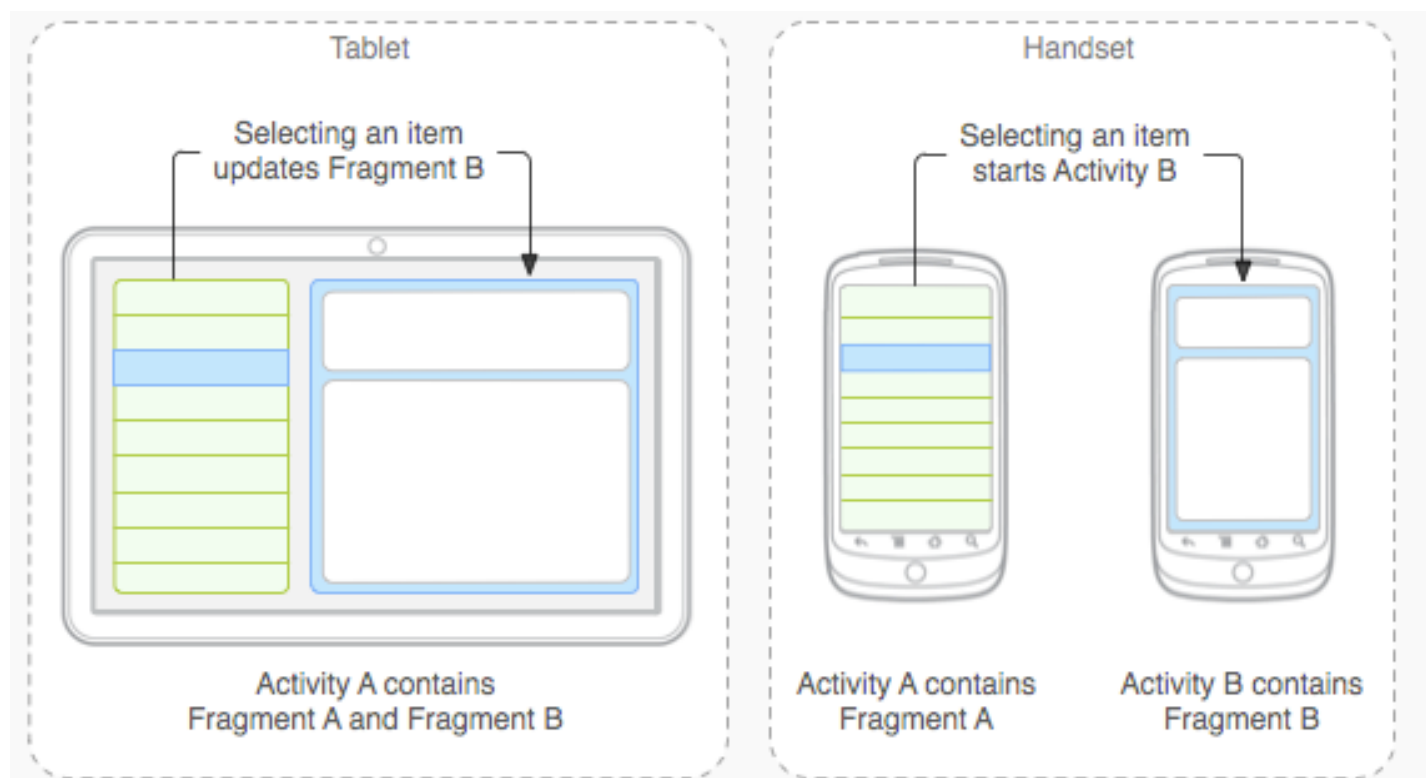

This means I can design the search to match exactly the fields of my database, which makes an SQL query very easy to build inside the app.

Activities

With my data in place, I could log out to the console to make sure the data was flowing correctly. This gave me some assurance that I was on the correct path to start to tackle the GUI side of Android platform, which is tied to activities. I started by reading the Android Documentation on activities and carefully looking at the activity lifecycle.

Showing Death Notices

As I now had data flowing in to the app, and I could see it was in my database, I could start to attempt to show this on-screen. I decided to go with standard Android activity-fragment layout, as this can suit both tablet and phones:

Showing how flexible fragments are. © Android Developer Documentation

Searching Death Notices

As planned, using SQLite to cache data locally made searching data notices a lot easier to perform. The downside is that I had a lot of options, any information I stored could be searched. I didn't want to do a general style all text search, but rather narrow down on fields that would be important to the user, namely:

- First Name

- Last Name
- Address

Example of Search Fields on RIP.ie, © RIP.ie

As mentioned before, I took a lot of cues from existing websites for death notices in Ireland. Some of these sites have expansive searches, and others less so. I decided to narrow focus on these as they make the most sense for the user and the platform. Text entry isn't the nicest thing to do on a touch screen, which is one of the reasons I started to consider a Map option.

Mapping Death Notices

When I came to create the activity for Google Maps, I realised two things were required:

- access to Google Maps API
- Geocoded addresses

since the addresses weren't geocoded from rip.ie, I had to think of a way of completing this. I decided like the scraping, I should do this in Ruby to keep the death notices application as lean as possible. It simply doesn't make sense for every users copy of the application to do this.

I needed to update my SQLite database (to accept latitude and longitude values) and again import the data from the server.

User Interface

For the user interface, I tried to stick to my initial design goals: very simple interface, big buttons and simple, descriptive language. To speed up development, I spent time mocking up the interface. This included a few ideas I didn't end up using (such as tabs for the main interface).

Mockups

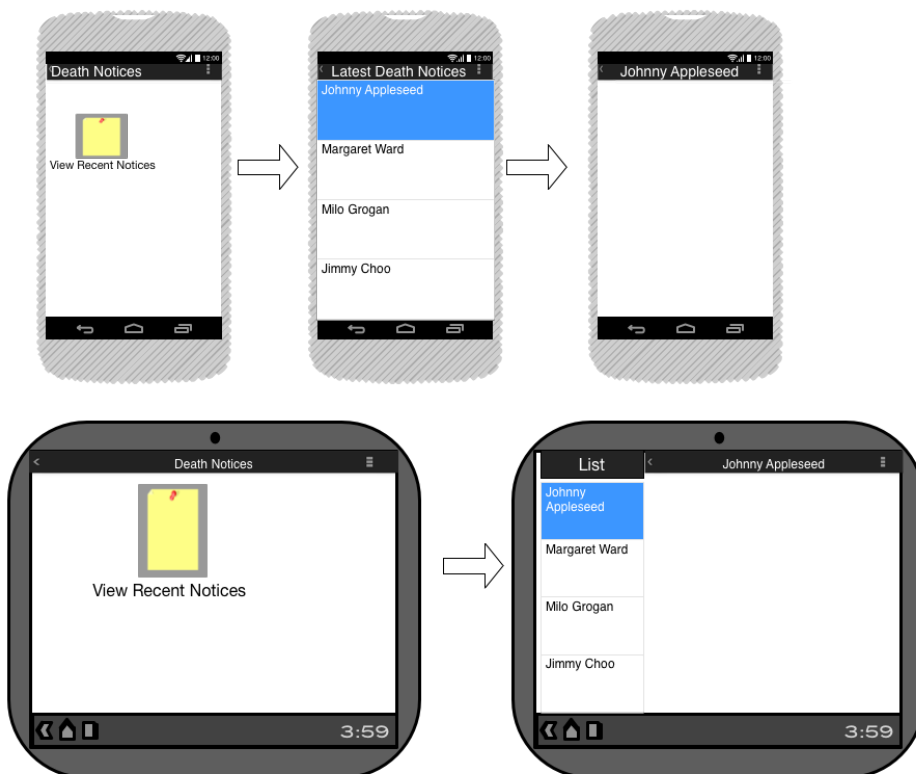

Start Screen

Final Thoughts

In the end, the design was highly constrained by the market it tries to serve. That was difficult from a development point of view, as I would have liked to add a lot more features (like social sharing).

Acknowledgments

Thanks to my friend Diarmuid O’Riordan for the initial idea to do a death notices application. Also thanks to my girlfriend Rebecca Cloono, who used the application and gave invaluable feedback. Lastly, a big thank you to my grandfather Desmond Muldowney, who I managed to watch using the application and gain valuable insights from (*as always*).
